Periodontal treatment is very effective in arresting / controlling gum disease in most pregnant women... especially in those women at high risk of pregnancy complications.

Non-surgical periodontal therapy (scaling & root planing):
- does control gum disease in most pregnant women
- does always remain safe during 2nd & 3rd trimesters
- but does NOT prevent complications
- does NOT eliminate gum inflammation completely
- does not completely prevent the start of complications during pregnancy
- successfully restores gum health
- successfully eliminates gum inflammation
- may prevent possible complications between gum disease and systemic diseases
- may prevent adverse pregnancy outcomes

Make sure that gum disease does not become an issue during pregnancy.
