Regenerative potential of leucocyte- and platelet-rich fibrin. Part A: intra-bony defects, furcation defects and periodontal plastic surgery. A systematic review and meta-analysis

Abstract

Aim: To analyse the regenerative potential of leucocyte- and platelet-rich fibrin (L-PRF) during periodontal surgery.

Materials and Methods: An electronic and hand search were conducted in three databases. Only randomized clinical trials were selected and no follow-up limitation was applied. Pocket depth (PD), clinical attachment level (CAL), bone fill, keratinized tissue width (KTW), recession reduction and root coverage (%) were considered as outcome. When possible, meta-analysis was performed.

Results: Twenty-four articles fulfilled the inclusion and exclusion criteria. Three subgroups were created: intra-bony defects (IBDs), furcation defects and periodontal plastic surgery. Meta-analysis was performed in all the subgroups. Significant PD reduction (1.1 ± 0.5 mm, p < 0.001), CAL gain (1.2 ± 0.6 mm, p < 0.001) and bone fill (1.7 ± 0.7 mm, p < 0.001) were found when comparing L-PRF to open flap debridement (OFD) in IBDs. For furcation defects, significant PD reduction (1.9 ± 1.5 mm, p = 0.01), CAL gain (1.3 ± 0.4 mm, p < 0.001) and bone fill (1.5 ± 0.3 mm, p < 0.001) were reported when comparing L-PRF to OFD. When L-PRF was compared to a connective tissue graft, similar outcomes were recorded for PD reduction (0.2 ± 0.3 mm, p > 0.05), CAL gain (0.2 ± 0.5 mm, p > 0.05), KTW (0.3 ± 0.4 mm, p > 0.05) and recession reduction (0.2 ± 0.3 mm, p > 0.05).

Conclusions: L-PRF enhances periodontal wound healing.

Key words: bone regeneration; gingival recession; intra-bony defects; leucocyte–platelet-rich fibrin; open flap debridement; platelet-rich fibrin; tissue regeneration

Accepted for publication 22 October 2016

In the last 20 years, platelet concentrates (PCs) have emerged as a potential regenerative material, used alone or as scaffold for other graft materials. PCs are blood extracts, obtained after processing a whole blood sample, mostly through centrifugation (Dohan et al. 2014a). In 1970, Matras (1970) published the first article on PCs using fibrin glue to improve skin wound healing. But it was not until Marx’s studies (Marx et al. 1998, Marx 2001) that the use of PCs also gained interest in oral and maxillofacial surgery. Since then,
different techniques have been developed and with them, a variety of preparations. The first PCs generation (Fig. 1) include platelet-rich plasma (PRP) and plasma rich in growth factors (PRGF). Their preparation requires anticoagulants at the moment of blood collection to avoid coagulation. Consequently, the fibrin polymerization occurs rapidly, resulting in a weak fibrin network (Dohan et al. 2006a). They are used as liquid solution or in gel form after adding bovine thrombin and calcium chloride. Due to the difficulties in the preparation and the inconsistent outcome of PRP and PRGF formulations, a second PCs generation was introduced in 2001 by Choukroun and co-workers (Choukroun 2001, Dohan et al. 2006a, 2014a). The use of platelet-rich fibrin (PRF) is simple and requires neither anticoagulant, bovine thrombin nor calcium chloride. It is nothing more than centrifuged blood without any additives (Table S1). Whole blood is centrifuged without anticoagulants, centrifuged at high spin so that three layers are obtained: red blood corpuscles (RBCs) at the bottom of the tube, platelet-poor plasma (PPP) on the top and an intermediate layer called “buffy coat” where most leucocytes and platelets are concentrated.

This Buffy coat or L-PRF is a bioactive construct that stimulates the local environment for differentiation and proliferation of stem and progenitor cells (Dohan et al. 2006b). It acts as an immune regulation node with inflammation control abilities, including a slow continuous release of growth factors over a period of 7–14 days (Dohan et al. 2006c). Rich in fibrin, platelets (±95% of initial blood), leucocytes (±50% of initial blood), monocytes and stem cells, L-PRF can be further transformed into a membrane, circa 1 mm in thickness, by careful compression (Dohan et al. 2010) (Appendix S1). Its strong fibrin architecture and its superior mechanical properties distinguish it from other kinds of PCs (Khorshidi et al. 2016). PRP, for example, has a thin and non-condensed fibrin network with a low tensile strength so that it is less useful as a space maintainer (Burnouf et al. 2013). The strong fibrin network in L-PRF is explained by the physiological concentrations of thrombin during its preparation. Rowe et al. (2007) concluded that a high thrombin concentration resulted in a high-interconnected fibre mesh with a fine fibre structure. However, as thrombin concentration decreased, fibre size increased as well as the mechanical properties. Apart from the biological and mechanical properties, antimicrobial effects have also been described (Yang et al. 2015).

The main aim of this systematic review was to study the beneficial effect of L-PRF used as sole filling material and as adjunct to conventional techniques in periodontal surgery.

Materials and Methods

The protocol of this systematic review was based on the guidelines of the Belgian Centre for Evidence-Based Medicine (CEBAM), Belgian Branch of the Dutch Cochrane Centre. It was conducted in accordance with the Transparent Reporting of Systematic Reviews and Meta-analyses (PRISMA statement, Moher et al. 2009).

Focused PICO question

The following statements were used to conduct the systematic search:
- Population (P) = systemically healthy humans (ASA I) with loss of periodontal tissues.
- Intervention (I) = use of L-PRF (protocol 2700 r.p.m./12 min. or 3000 r.p.m./10 min.) as sole biomaterial or in combination to other biomaterials in periodontal surgery.
- Comparison (C) = traditional techniques: open flap debridement with or without grafting, periodontal plastic surgery via coronally advanced flap, with or without connective tissue graft.
- Outcome (O) = alveolar bone and/or periodontal wound healing.

A PICO question was created to define the search strategy: **Does L-PRF promote periodontal wound healing in systemically healthy patients (ASA I) during periodontal surgery compared to traditional techniques?**

Search strategy

An electronic search was performed in three Internet databases: the National Library of Medicine, Washington, DC (MEDLINE-PubMed), EMBASE (Excerpta Medical Database by Elsevier), and Cochrane Central Register of Controlled Trials (CENTRAL). The search terms were defined by combining (Mesh Terms OR Key Words) from “Population” AND (Mesh Terms OR Key Words) from...
“Intervention”, as shown in Table S2. The search was limited to studies involving humans. No language or time restrictions were applied in the first search. However, only studies in English were included for selection. No follow-up limitations were used. The last electronic search was performed on the 31st of July 2015.

This search was enriched by hand searches, citation screening and expert recommendations. All reference lists of selected papers as well as related reviews were scanned for possible additional studies.

Screening and selection
The titles and abstracts obtained from the first search were screened independently by two reviewers (A.C., N.M.). When publications did not meet the inclusion criteria, they were excluded upon reviewer’s agreement. Any disagreement between the two reviewers was resolved by discussion. All full texts of the eligible articles were obtained and examined by both reviewers. The articles that fulfilled all selection criteria were processed for data extraction. Given some variability in the preparation of L-PRF, two different protocols (2700 r.p.m./12 min. or 3000 r.p.m./10 min.) were included. The inclusion and exclusion criteria are summarized in Table S3.

Assessment of heterogeneity
The heterogeneity of the included studies was judged based on following factors: (1) study design and evaluation period, (2) subject characteristics and smoking habits, and (3) surgical protocol used: (a) centrifugation protocol (2700 r.p.m./12 min. or 3000 r.p.m./10 min.), (b) mL blood used to prepare L-PRF and (c) number of clots/membranes (if used).

Quality assessment
The quality assessment, performed by both reviewers (A.C., N.M.), was based on the Cochrane Collaboration’s tool for assessing risk of bias. Six quality criteria were verified: (1) sequence generation or randomization component, (2) allocation concealment, (3) blinding of participants, personnel and outcome assessors, (4) incomplete/missing outcome data, (5) selective outcome reporting and (6) other sources of bias. In case of any doubt, the authors were contacted for clarification or to provide missing information. Low risk of bias was indicated if all quality criteria were “present”, moderate risk of bias if one or more key domains were “unclear” and high risk of bias if one or more key domains were “absent”.

Data analysis
The analysed variables were as follows: pocket depth (PD) reduction, clinical attachment level (CAL) gain, bone fill (mm and %), keratinized tissue width (KTW) gain, tissue thickness gain, recession reduction and root coverage (%) at 6 months. For all variables in each group, mean values and standard deviation (SD) were extracted. All data were arranged in groups for the intergroup comparison (L-PRF versus control group). When possible, a meta-analysis was performed. The mean difference was calculated and a 95% confidence interval (CI) was computed. Forest plots were created to display the analysis.

Results
Search and selection
As a result of the electronic and hand search, 205 articles were obtained, of which 23 were duplicate and consequently removed (Fig. 2). A total of 182 articles was included for title and abstract screening. From those, 25 articles were included for full text review. One article was excluded after full text screening, which was conducted independently by two reviewers (A.C., N.M.) (Table S4). Twenty-four randomized control trials (RCTs) fulfilled the inclusion criteria and were included for analysis.

The included articles were classified into three subgroups, depending on the indication for the use of L-PRF (Tables 1–3):
Intra-bony defect fill: \( n = 13 \)
- L-PRF versus PRP versus OFD: \( n = 1 \), Pradeep et al. (2012).
- L-PRF versus bovine porous bone mineral (BPHM): \( n = 1 \), Lekovic et al. (2012).
- L-PRF versus demineralized freeze-dried bone allograft (DFDBA): \( n = 3 \), Bansal & Bharti (2013), Shah et al. (2015), and Agarwal et al. (2016).
- L-PRF versus Emdogain®, \( n = 1 \), Gupta et al. (2014).
- L-PRF versus autologous bone graft (ABG): \( n = 1 \), Mathur et al. (2015).

Furcation defects: \( n = 2 \), Sharma & Pradeep (2011a), and Bajaj et al. (2013).

Periodontal plastic surgery: \( n = 9 \)
- Coronally advanced flap (CAF) versus CAF + L-PRF: \( n = 4 \), Arora et al. (2009), Padma et al. (2013), Gupta et al. (2015), and Thamaraiselvan et al. (2015).
- CAF + L-PRF versus CAF + Emdogain® (EMD): \( n = 1 \), Jankovic et al. (2010).

Assessment of heterogeneity

Study design and evaluation period

All studies were RCTs and frequently presented a split-mouth design. The articles with these characteristics are the following: intra-bony defects (IBDs) 7/13 (Lekovic et al. 2012, Rosamma et al. 2012, Bansal & Bharti 2013, Ajwani et al. 2015, Elgendy & Abo Shady 2015, Shah et al. 2015, Agarwal et al. 2016), furcation defects 1/2 (Sharma & Pradeep 2011a), plastic surgery 7/9 (Arora et al. 2009, Jankovic et al. 2010, 2012, Padma et al. 2013, Eren & Atilla 2014, Keceli et al. 2015, Tunali et al. 2015). The follow-up ranged slightly (IBDs 6–12 months, furcation defects 9 months and plastic surgery 6–12 months).

Subject characteristics and smoking habits

Healthy subjects with no active periodontal disease were included in all the studies. The studies that did not include smokers are the following: IBDs 9/13 (Sharma & Pradeep 2011a, b, Lekovic et al. 2012, Rosamma et al. 2012, Pradeep et al. 2012, Pradeep et al. 2015, Gupta et al. 2014, Ajwani et al. 2015, Shah et al. 2015, Agarwal et al. 2016), furcation defects 1/2 (Sharma & Pradeep 2011a), plastic surgery 8/9 (Jankovic et al. 2010, 2012, Padma et al. 2013, Eren & Atilla 2014, Gupta et al. 2015, Eren & Atilla 2015, Keceli et al. 2015, Thamaraiselvan et al. 2015, Tunali et al. 2015).

Surgical protocol

A wide variety of surgical protocols was used. This heterogeneity can be derived from Tables 1–3.

Quality assessment

Appendix S2–S4 shows the quality assessment for the included studies. All articles on furcation defects and periodontal plastic surgery showed a moderate risk of bias. Similarly, 12 articles using L-PRF in IBD had a moderate risk, and one had a low risk of bias.

Quantitative assessment

The extracted data were continuous. The articles with split-mouth design and parallel design were not analysed separately. The control group and test group from the articles with split-mouth design were considered as independent. As shown in the Figs 3 and 4, the studies with split-mouth design do not differ from those with parallel design. Random effects were used due to the heterogeneity of the data.

Intra-bony defects

In the articles on IBDs, benefits in terms of PD reduction, CAL gain and bone fill were shown when L-PRF was used alone or in combination with other biomaterials (Table 1). Six out of 13 articles (Sharma & Pradeep 2011b, Thorat et al. 2011, Pradeep et al. 2012, 2015, Rosamma et al. 2012, Ajwani et al. 2015) could be used for a meta-analysis since they reported on similar outcome measures comparing OFD to OFD + L-PRF (Fig. 3a–c). The meta-analysis of IBDs showed a statistical significant difference for PD reduction (mean difference: 1.1 mm, \( p < 0.001 \), CI: 0.6–1.6), CAL gain (mean difference: 1.2 mm, \( p < 0.001 \), CI: 0.5–1.9), amount of bone fill in mm (mean difference: 1.7 mm, \( p < 0.001 \), CI: 1.0–2.3) and bone fill when scored as % (mean difference: 46.0%, \( p < 0.001 \), CI: 33.2–58.7), all in favour of L-PRF.

Furcation defects

Two articles were included for furcation defects (Sharma & Pradeep 2011a, Bajaj et al. 2013). A meta-analysis could be performed for both articles, comparing OFD to OFD + L-PRF (Fig. 3d,e). Statistical significant differences could be found for PD reduction (mean difference: 1.9 mm, \( p = 0.01 \), CI: 0.4–3.5), CAL gain (mean difference: 1.3 mm, \( p < 0.001 \), CI: 0.8–1.7), amount of bone fill in mm (mean difference: 1.5 mm, \( p < 0.001 \), CI:1.2–1.9), bone fill when scored as % (37.6%, \( p < 0.001 \), CI: 30.6–44.5), again in favour of L-PRF (Table 2).

Periodontal plastic surgery

In case of a CAF, some studies reported some benefits when L-PRF membranes were added, but others failed to show this advantage (Table 3). When the use of a CTG in a CAF procedure was compared to the use of L-PRF membranes, similar results were obtained. Two meta-analyses could be performed, one comparing a CAF alone versus a CAF with L-PRF, and another comparing a CAF with L-PRF versus a CAF with a CTG. The following variables were considered: PD reduction, CAL gain, KTW gain, tissue thickness gain, recession reduction and root coverage at 6 months.

For the first comparison (CAF + L-PRF versus CAF, Fig. 4a,b), three articles could be included for a meta-analysis (Arora et al. 2009, Gupta et al. 2015, Thamaraiselvan et al. 2015). The analysis showed no
Table 1. L-PRF for intra-bony defects. Papers have been arranged by subapplications (L-PRF + OFD versus OFD, L-PRF versus PRP, L-PRF versus L-PRF + BPBM, L-PRF + DFDBA versus DFDBA, L-PRF versus Emdogain®, L-PRF versus nano-bone®, L-PRF versus ABG, L-PRF in furcation lesions: L-PRF + OFD versus OFD).

ABG, autologous bone graft; BPBM, Bovine porous bone mineral; C, control group; CAL, clinical attachment level; DFDBA, demineralized freeze-dried bone allograft; IBDs, intra-bony defects; NSS, no statistically significant; OFD, open flap debridement; PD, pocket depth; PRP, platelet-rich plasma; REC, gingival recession; SS, statistically significant; T, test group.

<sup>a</sup>Process protocol, Nice, France.
<sup>b</sup>KW-70, AlmicroTM Instruments, Ambala Cantt., Haryana, India.
<sup>c</sup>R-4C, REMI, Mumbai, India.
<sup>d</sup>Labofuge 300, Kendro Laboratory Products GmbH, Osterrode, Germany.
statistical significant difference in PD reduction (mean difference: 0.2 mm, \( p = 0.2 \), CI: \(-0.08 \) to \(0.4\)), CAL gain (mean difference: 0.4 mm, \( p = 0.09 \), CI: \(-0.06 \) to \(0.8\)), KTW gain (mean difference: 0.3 mm, \( p = 0.1 \), CI: \(-0.06 \) to \(0.6\)), tissue thickness (mean difference: 0.2 mm, \( p = 0.09 \), CI: \(-0.03 \) to \(0.4\)) and root coverage at 6 months (mean difference: 9.6%, \( p = 0.6 \), CI: \(-23.2 \) to \(42.4\)), although the results showed a trend that L-PRF was superior for all of these variables. However, statistically significant difference could be found for recession depth reduction (mean difference: 0.6 mm, \( p < 0.01 \), CI: \(-0.2 \) to \(1.1\)), in favour of the for the L-PRF treatment.

For the second comparison (CAF + L-PRF versus CAF + CTG, Fig. 4c) also three articles could be used for a meta-analysis (Jankovic et al. 2012, Eren & Atilla 2014, Tunali et al. 2015). No statistical significant differences could be found for all of the variables: PD reduction (mean difference: 0.2 mm, \( p = 0.4 \), CI: \(-0.5 \) to \(0.2\)), CAL gain (mean difference: 0.2 mm, \( p = 0.3 \), CI: \(-0.3 \) to \(0.7\)), KTW gain (mean difference: 0.3 mm, \( p = 0.2 \), CI: \(-0.7 \) to \(0.2\)) and recession reduction (mean difference: 0.2 mm, \( p = 0.2 \), CI: \(-0.4 \) to \(0.1\)). Root coverage could not be included in this meta-analysis since only one article (Jankovic et al. 2012) fully analysed this variable; Eren & Atilla (2014), and Tunali et al. (2015) did not include the standard deviations.

The adverse events were only registered in some articles within the group of periodontal plastic surgery (Aroca et al. 2009, Jankovic et al. 2010, 2012, Eren & Atilla 2014, Gupta et al. 2015). Each article analysed the adverse events with a different scale, so no meta-analysis could be performed. Five out of the nine articles on periodontal plastic surgery reported on pain, swelling and hypersensitivity. All of them observed less side effects in L-PRF sites.

**Discussion**

L-PRF has often shown a positive effect when applied during periodontal surgery. Although it has been classified as a platelet concentrate (Dohan et al. 2014a), it can also be considered as a living tissue graft due to its cellular content and its constant

release of growth factors for more than 7 days (Dohan et al. 2006b).

This review demonstrates that L-PRF has many applications but there is no clear standard protocol per surgical procedure. For example, the number of clots used varies enormously, as well as the amount of blood drawn to prepare L-PRF. The type of centrifuge and setting also differed from one study to another. More standardized protocols are necessary in order to better compare and standardize outcomes.

The effectiveness of L-PRF in the treatment of intra-bony defects has been studied by different research groups (Rock 2013, Shah et al. 2014).
In these studies, L-PRF was placed in the defect and L-PRF membranes were used to cover the defect similar to a guided tissue regeneration (GTR) membrane. Clinical and radiographic evaluations showed statistically significant greater PD reduction, CAL gain and radiographic intra-bony defect fill in the L-PRF group (Table 3). Different graft materials were also compared to L-PRF during GTR. The outcomes showed a favourable effect of L-PRF in all clinical parameters measured, or an improvement of the outcomes in studies where L-PRF was combined with other biomaterials (Table 3).

Although very limited data exist, the use of L-PRF in furcation defects has also shown favourable results.

For periodontal plastic surgery, the comparison of CAF + L-PRF versus CAF led to controversial results. Although most articles did not show statistically significant differences, L-PRF was superior for all of the parameters recorded. Comparing CAF + L-PRF versus CAF + CTG, L-PRF might be an alternative to a connective tissue graft. The latter is supported by some case reports (Anilkumar et al. 2009, Agarwal et al. 2013, Singh & Bharti 2013). In this systematic review, a mean root coverage of 86.5% at 6 months has been recorded for CAF + L-PRF treatment. For CAF + EMD and CAF + CTG, a mean root coverage of 91.2% and 90.3% was, respectively, reported in a recent systematic review at 6 months (Cairo et al. 2008).

Some limitations have to be taken into consideration while processing this systematic review. Most of the included articles showed a moderate risk of bias. In those articles, the power analysis was often performed after the recruitment of the participants, where for a RCT it should be done prior to the recruitment in order to determine the sample size. Working in the opposite way, a selective outcome reporting bias can be introduced. Additionally, the allocation concealment and blinding methods were frequently not applied which increased the risk of bias.

Meta-analysis could be performed in the three indications. However, also here the results of certain studies have to be considered very cautiously. For instance, for the IBDs subgroup, Ajwani et al. (2015) obtained the worst results compared to the rest of the selected articles. The reason could be that two- and three-wall IBDs were included but not analysed separately. Moreover, only one L-PRF clot without membrane was used, so the stability of one L-PRF clot in a two-wall defect without the use of a membrane might not have been ideal. Given the importance of stability in GTR, the use of L-PRF clots in two- or one-wall defects should be accompanied by a L-PRF membrane. In periodontal plastic surgery, Arora et al. (2009) published the only article that reported better outcome for the control group (CAF). However, smokers (<20 cig/day) were also included, though smoking negatively influences the healing process and affects
complete root coverage (Chambrière et al. 2009, De Sanctis & Clementini 2014). Tobacco smoke might directly affect the peripheral blood cells within the L-PRF (Armilli et al. 2012), yielding to uncertain outcomes.

Regardless the limitations of the included studies, it is worth pointing out some strengths of this systematic review. A total number of 722 participants was enrolled in the selected studies (479 in intra-bony defects, 55 in furcation defects, 188 in periodontal plastic surgery). Taking into consideration the rather short history of L-PRF, this review comprehends a quite large sample of patients. Moreover, the follow-up varied slightly in the articles included for meta-analysis. The duration in the follow-up ranged from 9 to 12 months in the studies selected for quantitative assessment for the IBGs group. Considering furcation defects and periodontal plastic surgery, all of them had a follow-up of 9 and 6 months, respectively. Moreover, only the two most accepted protocols of centri-

fugation (3000 r.p.m./10 min. or 2,700 r.p.m./12 min.) were included. All other protocols that were not explained in detail or with a non-standardized procedure were excluded. A correct handling of L-PRF is of the utmost importance. It should be clearly distinguished what L-PRF is and what not. For example, L-PRF and PRP contain different cell concentrations, release different amount of growth factors, and have different mechanical properties although both come from a blood sample (Dohan et al. 2006a).

Conclusion

Favourable effects on hard and soft tissue healing and postoperative discomfort reduction were often reported when L-PRF was used. Nevertheless, standardization of the protocol is needed to obtain an optimal effect of L-PRF in regenerative procedures. Correct handling of L-PRF as well as the use of enough clots/membranes per surgical site might be crucial to obtain benefits from this technique. This biomaterial can be taken into consideration due to its reported good biological effects, low costs and ease of preparation.

Clinical Relevance

Scientific rationale for the study: The aim of this systematic review and meta-analysis is to extensively analyse the additional regenerative potential of L-PRF during periodontal surgery.

Principal findings: The meta-analysis showed significant clinical benefits of L-PRF for the treatment of IBDs and for furcation defects, and similar outcomes when a connective tissue graft (CTG) was replaced by L-PRF membranes during periodontal plastic surgery.

Practical implications: These results indicate that L-PRF has favourable effects periodontal wound healing, and postoperative discomfort reduction. Nevertheless, standardization of the protocol is needed to obtain an optimal effect.
